

THE BOUNDARY OF THE KREIN SPACE TRACIAL NUMERICAL RANGE, AN ALGEBRAIC APPROACH AND A NUMERICAL ALGORITHM

N. BEBIANO, H. NAKAZATO, A. NATA AND J. DA PROVIDÊNCIA

ABSTRACT: In this article, tracial numerical ranges associated with matrices in an indefinite inner product space are investigated. The boundary equations of these sets are obtained and the case of the boundary being a polygon is studied. As an application, a numerical algorithm for plotting the tracial numerical range of an arbitrary complex matrix, is presented. Our approach uses the elementary idea that the boundary may be traced by computing the supporting lines.

KEYWORDS: Numerical range, indefinite inner product, J -Hermitian matrix, non-interlacing eigenvalues.

AMS SUBJECT CLASSIFICATION (2000): 47A12, 46C20.

1. Introduction

Let J be a Hermitian involutive matrix (i.e., $J^* = J$, $J^2 = I_n$), with *signature* $(r, n - r)$, $0 \leq r \leq n$ (i.e., with r positive and $n - r$ negative eigenvalues). We consider \mathbb{C}^n endowed with the indefinite inner product defined by $[x, y] = y^* J x$, $x, y \in \mathbb{C}^n$. A matrix $H \in M_n$, the algebra of $n \times n$ complex matrices, is J -Hermitian if $H^\# = H$, where $H^\# = J H^* J$ is the J -adjoint of H . A matrix $U \in M_n$ is said to be J -unitary if $U^\# U = U U^\# = I_n$. The J -unitary matrices form a locally compact connected group denoted by $\mathcal{U}_{r, n-r}$ and called the J -unitary group. In the case $r = n$, $\mathcal{U}_{n, 0} = \mathcal{U}_n$ is the *unitary group*, which is a compact group. For $C, A \in M_n$, the J -tracial numerical range of A is denoted and defined as

$$W_C^J(A) = \{ \operatorname{tr} (C U A U^{-1}) : U \in \mathcal{U}_{r, n-r} \}. \quad (1)$$

This set is a connected set in the Argand plane \mathbb{C} and satisfies the symmetry property $W_C^J(A) = W_A^J(C)$ (see [1], [6] for other properties). If $r = n$, $W_C^J(A)$ is the C -numerical range of A simply denoted by $W_C(A)$. Hausdorff [3] proved the convexity of $W_C(A) = W(A)$ in the case C is a rank one orthogonal projection. Using Morse theory, Westwick [10] proved the convexity of $W_C(A)$

for C Hermitian, and in [8] Poon gave an alternative proof using majorization techniques. In [9], Tam generalized Westwick's theorem for certain compact Lie groups and recently [7], a convexity result for $W_C^J(A)$ has been proved applying Morse theory.

We recall that the spectrum of a J -Hermitian matrix is symmetric with respect to the real axis. In this note, to avoid trivial cases we mainly consider J -Hermitian matrices with real spectra. In the sequel the following notation will be used:

$$\sigma_+^J(A) = \{\lambda \in \mathbb{C} : A\xi = \lambda\xi, \text{ for some } \xi \in \mathbb{C}^n, [\xi, \xi] > 0\}, \quad (2)$$

$$\sigma_-^J(A) = \{\lambda \in \mathbb{C} : A\xi = \lambda\xi, \text{ for some } \xi \in \mathbb{C}^n, [\xi, \xi] < 0\}. \quad (3)$$

The eigenvalues of A are said to be *noninterlacing* if

$$\max \sigma_-^J(A) < \min \sigma_+^J(A) \quad \text{or} \quad \max \sigma_+^J(A) < \min \sigma_-^J(A). \quad (4)$$

Replacing in (4) $<$ by \leq the eigenvalues are said to be *weakly noninterlacing*. Noninterlacing property plays a key role in the development of the theory of numerical ranges associated with non-compact groups.

Let $\Re^J(A) = (A + A^\#)/2$ and $\Im^J(A) = (A - A^\#)/2i$ be the unique J -Hermitian matrices such that $A = \Re^J(A) + i\Im^J(A)$. If $J = I_n$ this reduces to the well-known cartesian decomposition of A , $A = \Re(A) + i\Im(A)$, where $\Re(A) = (A + A^*)/2$ and $\Im(A) = (A - A^*)/2i$. Throughout, C will denote a J -Hermitian matrix with noninterlacing eigenvalues:

$$\sigma_+^J(C) = \{c_1 \geq \cdots \geq c_r\}, \quad \sigma_-^J(C) = \{c_{r+1} \geq \cdots \geq c_n\},$$

$$c_n > c_1 \quad \text{or} \quad c_r > c_{r+1}.$$

Under these hypothesis C is J -unitarily diagonalizable, that is, diagonalizable under a J -unitary similarity transformation. In [7] it has been proved that if there exists $\theta \in [\theta_1, \theta_2] \subset \mathbb{R}$ such that $H_\theta := \Re^J(e^{-i\theta}A)$ has real noninterlacing eigenvalues

$$\sigma_+^J(H_\theta) = \{\lambda_1(\theta) \geq \cdots \geq \lambda_r(\theta)\}, \quad \sigma_-^J(H_\theta) = \{\lambda_{r+1}(\theta) \geq \cdots \geq \lambda_n(\theta)\},$$

$$\lambda_n(\theta) > \lambda_1(\theta) \quad \text{or} \quad \lambda_r(\theta) > \lambda_{r+1}(\theta),$$

then $W_C^J(A)$ is a closed convex set in \mathbb{C} contained in a closed cone

$$\{z_0 + re^{i\eta} : r \geq 0, \eta_1 \leq \eta \leq \eta_2\}$$

with $0 \leq \eta_2 - \eta_1 < \pi$.

This paper is organized as follows. The boundary equations of $W_C^J(A)$ are deduced in Section 2. In Section 3, $W_C^J(A)$ is studied for A a J -normal matrix. As an heuristic tool, it is convenient to have a code to produce the plot of $W_C^J(A)$. In Section 4 an algorithm to plot $W_C^J(A)$ is presented. Our approach uses the elementary idea that the boundary of $W_C^J(A)$ may be traced by computing the supporting lines of $W_C^J(A)$.

2. On the boundary of $W_C^J(A)$

Theorem 2.1. *Let $J = I_r \oplus -I_{n-r}$, $0 < r < n$, $C = \text{diag}(c_1, \dots, c_n)$ with $c_1 > \dots > c_r \in \sigma_+^J(C)$, $c_{r+1} > \dots > c_n \in \sigma_-^J(C)$ and $c_n > c_1$. Let $A \in M_n$ be a non J -normal matrix. Assume that there exists $\theta \in [\theta_1, \theta_2]$ such that the J -Hermitian matrix $\Re^J(e^{-i\theta} A)$, has real simple and noninterlacing eigenvalues:*

$$\lambda_1(\theta) > \dots > \lambda_r(\theta) > \lambda_{r+1}(\theta) > \dots > \lambda_n(\theta).$$

Then the function $\Lambda(\theta) = \sum_{j=1}^n c_j \lambda_j(\theta)$ is convex in the domain

$$\{re^{i\theta} : r > 0, \theta_1 < \theta < \theta_2\},$$

and the curve parametrized by

$$\begin{cases} x(\theta) = \cos \theta \Lambda(\theta) - \sin \theta \Lambda'(\theta) \\ y(\theta) = \sin \theta \Lambda(\theta) + \cos \theta \Lambda'(\theta) \end{cases}, \quad \theta \in [\theta_1, \theta_2],$$

is contained in $\partial W_C^J(A)$.

Proof. Let $A = H + iK$ be a non J -normal matrix, where $H = \Re^J(A)$ and $K = \Im^J(A)$. Under the hypothesis, the J -Hermitian matrix $\Re^J(e^{-i\theta} A) = \cos \theta H + \sin \theta K$ has real simple eigenvalues for $\theta \in [\theta_1, \theta_2]$. Then there exists a J -orthonormal basis in \mathbb{C}^n , $\{\xi_1(\theta), \dots, \xi_n(\theta)\}$, satisfying $\Re^J(e^{-i\theta} A)\xi_j(\theta) = \lambda_j(\theta)\xi_j(\theta)$, $j = 1, \dots, n$. According to the hypothesis and by Theorem 1.1 of [1]

$$W_C^J(\Re^J(e^{-i\theta} A)) = \left(-\infty, \sum_{j=1}^n c_j \lambda_j(\theta) \right].$$

The eigenvalue $\lambda_j(\theta)$ is an analytic function of θ . Since the eigenvalues are simple, we may assume that $\xi_j(\theta)$ is an analytic function of θ . The image of

the map $\phi : [\theta_1, \theta_2] \rightarrow \mathbb{C}$ defined by

$$\begin{aligned}\phi(\theta) &= u(\theta) + iv(\theta) \\ &= \sum_{j=1}^n c_j e^{i\theta} \left[\frac{[(\Re^J(e^{-i\theta}A)\xi_j(\theta), \xi_j(\theta))]}{[\xi_j(\theta), \xi_j(\theta)]} + i \frac{[(\Im^J(e^{-i\theta}A)\xi_j(\theta), \xi_j(\theta))]}{[\xi_j(\theta), \xi_j(\theta)]} \right]\end{aligned}$$

is contained in the boundary of $W_C^J(A)$. The dual curve of the curve $\phi(\theta)$, that is, the family of tangent lines of the curve $\phi(\theta)$, may be defined in an interval $[\theta_1, \theta_2]$ on which $\phi'(\theta) \neq 0$. The dual curve is given by

$$\left\{ \left(1, \frac{-v'(\theta)}{u(\theta)v'(\theta) - v(\theta)u'(\theta)}, \frac{u'(\theta)}{u(\theta)v'(\theta) - v(\theta)u'(\theta)} \right) : \theta_1 < \theta < \theta_2 \right\}.$$

The homogeneous expression of the dual curve L is given by

$$\left\{ \left(\sum_{j=1}^n c_j \lambda_j(xH + yK), -x, -y \right) : (x, y) \in \mathbb{R}^2 \right\}.$$

In an nonhomogeneous form, the dual curve is given by

$$\tilde{L} = \left\{ \left(-x^{-1} \sum_{j=1}^n c_j \lambda_j(xH + yK), 1, \frac{y}{x} \right) : \arctan \theta_1 < \frac{y}{x} < \arctan \theta_2 \right\},$$

or by

$$L = \left\{ \left(1, \frac{-\cos \theta}{\sum_{j=1}^n c_j \lambda_j(\theta)}, \frac{-\sin \theta}{\sum_{j=1}^n c_j \lambda_j(\theta)} \right) : \theta_1 < \theta < \theta_2 \right\}.$$

Next we show that the function

$$f(x, y) = x f\left(1, \frac{y}{x}\right) = \sum_{j=1}^n c_j \lambda_j(xH + yK)$$

is convex in the domain $\{re^{i\theta} : r > 0, \theta_1 < \theta < \theta_2\}$.

For simplicity we denote $f(1, y/x)$ by $f(y/x)$, and so the proof of the convexity of the positive homogeneous function $f(x, y)$ reduces to the proof of the convexity of $f(y/x)$.

Suppose that $J = I_r \oplus -I_{n-r}$ and let $H = \text{diag}(\lambda_1, \dots, \lambda_r, \lambda_{r+1}, \dots, \lambda_n)$ with $\lambda_1 > \lambda_2 > \dots > \lambda_r > \lambda_{r+1} > \dots > \lambda_n$ being $K = (\mu_{tj})$. We set

$\mu_{tt} = \mu_t$. Then we have

$$\lambda_t(H + yK) = \lambda_t + y\mu_t + y^2 \sum_{1 \leq j \leq r, j \neq t} \frac{-|\mu_{tj}|^2}{\lambda_j - \lambda_t} + y^2 \sum_{r+1 \leq j \leq n} \frac{|\mu_{tj}|^2}{\lambda_j - \lambda_t} + O(y^3),$$

for $t = 1, 2, \dots, r$ and

$$\lambda_t(H + yK) = \lambda_t + y\mu_t + y^2 \sum_{1 \leq j \leq r} \frac{|\mu_{tj}|^2}{\lambda_j - \lambda_t} + y^2 \sum_{r+1 \leq j \leq n, j \neq t} \frac{-|\mu_{tj}|^2}{\lambda_j - \lambda_t} + O(y^3),$$

for $t = r + 1, r + 2, \dots, n$. Hence we obtain

$$\begin{aligned} f(y) &= \sum_{t=1}^n c_t \lambda_t(H + yK) = \sum_{t=1}^n c_t \lambda_t + y \sum_{t=1}^n c_t \mu_t + y^2 \sum_{1 \leq t < j \leq r} \frac{c_t - c_j}{\lambda_t - \lambda_j} |\mu_{tj}|^2 \\ &\quad + y^2 \sum_{r+1 \leq t < j \leq n} \frac{c_t - c_j}{\lambda_t - \lambda_j} |\mu_{tj}|^2 + y^2 \sum_{r+1 \leq t \leq n, 1 \leq j \leq r} \frac{c_j - c_t}{\lambda_t - \lambda_j} |\mu_{tj}|^2 + O(y^3) \end{aligned}$$

and so the function $f(y)$ satisfies

$$\begin{aligned} \frac{1}{2} f''(0) &= \sum_{1 \leq t < j \leq r} \frac{c_t - c_j}{\lambda_t - \lambda_j} |\mu_{tj}|^2 + \sum_{r+1 \leq t < j \leq n} \frac{c_t - c_j}{\lambda_t - \lambda_j} |\mu_{tj}|^2 \\ &\quad + \sum_{r+1 \leq t \leq n, 1 \leq j \leq r} \frac{c_j - c_t}{\lambda_t - \lambda_j} |\mu_{tj}|^2 \geq 0. \end{aligned}$$

Thus, the function $f(y)$ is locally convex at the origin. Since every point $(x, y) \neq (0, 0)$ can be rotated to a point $(x_0, 0)$ we may conclude that the function $\sum_{j=1}^n c_j \lambda_j(xH + yK)$ is convex in the mentioned domain and the above curve \tilde{L} does not have flexes. \square

Remark 2.1. (i) The curve $\{x(\theta) + iy(\theta) : \theta \in [\theta_1, \theta_2]\}$ in Theorem 2.1 is called the *boundary generating curve* of $W_C^J(A)$.

(ii) The assumption of $\Re^J(e^{-i\theta}A)$ having noninterlacing eigenvalues implies that either $\lambda_r(\theta) > \lambda_{r+1}(\theta)$ or $\lambda_n(\theta) > \lambda_1(\theta)$. By an appropriate choice of θ (i.e., substituting θ by $\theta + \pi$), we can reduce the second alternative to the first one and so without loss of generality we treat only one of them.

Theorem 2.2. *Let $A \in M_n$, and let J, C be under the conditions of Theorem 2.1. If the eigenvalues of C are all distinct and there exists at least one corner in $W_C^J(A)$, then A is J -normal.*

Proof. For any real t and S a J -Hermitian matrix, $\exp(itS) = I + itS + \theta(t^2)$ is J -unitary. Let $z = \text{tr}(AC)$ be a corner. It can be easily seen that $\text{tr}(S[C, A]) = 0$. For $A = H + iK$, and $\theta \in [\theta_1, \theta_2]$, we have $[C, \Re^J(e^{-i\theta}A)] = 0$. Thus $[C, H] = [C, K] = 0$, which implies that H, K can be expressed as polynomials in C and so A is J -normal. \square

Corollary 2.3. *Let J, C be under the conditions of Theorem 2.2 and let $A \in M_n$ be non J -normal. Then $W_C^J(A)$ is a $C^{(1)}$ -regular curve.*

Proof. Since $W_C^J(A)$ is convex, the nondifferentiable points of its boundary are corners. If there exists at least one corner, by Theorem 2.2, A is J -normal, a contradiction. \square

By Tarski-Seidenberg theorem [7], the boundary of $W_C^J(A)$ lies in an algebraic curve. An exact algorithm to provide the equation of an algebraic curve containing $\partial W_C^J(A)$ is given by a similar method to the one in [2] due to Chien and Nakazato.

Example 2.1. Let $J = I_2 \oplus -I_1$, $C = \text{diag}(1, 0, -1)$ and let

$$A = \begin{pmatrix} 2 & i & 0 \\ i & 1 & i \\ 0 & -i & -2 \end{pmatrix}.$$

The boundary of $W_C^J(A)$ lies in an algebraic curve $L(X, Y) = 0$ of order 16. The polynomial $L(X, Y)$ is given by

$$\begin{aligned} L(X, Y) = & -19683X^{12}Y^4 + 76545X^{10}Y^6 - 79542X^8Y^8 - 8155X^6Y^{10} \\ & + 26514X^4Y^{12} + 8505X^2Y^{14} + 729Y^{16} + 1250964X^{10}Y^4 - 2579850X^8Y^6 \\ & + 2632812X^6Y^8 - 2244970X^4Y^{10} - 315900X^2Y^{12} + 73710Y^{14} \\ & - 30362202X^8Y^4 + 28179060X^6Y^6 - 2850861X^4Y^8 + 8523515X^2Y^{10} \\ & + 1233531Y^{12} - 186624X^{10} + 786240X^8Y^2 + 344964500X^6Y^4 \\ & - 101340750X^4Y^6 - 138483138X^2Y^8 - 32015970Y^{10} + 11321856X^8 \\ & - 25683840X^6Y^2 - 1775064187X^4Y^4 - 98335965X^2Y^6 + 131658345Y^8 \\ & - 255820032X^6 + 269156160X^4Y^2 + 3366850448X^2Y^4 + 323668800Y^6 \\ & + 2578065408X^4 - 920666880X^2Y^2 - 2084332032Y^4 - 10407481344X^2 \\ & - 603832320Y^2 + 8074100736. \end{aligned} \tag{5}$$

We briefly describe how this polynomial is obtained. The curve $L(X, Y) = 0$ is defined as the dual curve of an algebraic curve $M(1, x, y) = 0$ of order 6. A generic point (X_0, Y_0) of the curve $L(X, Y) = 0$ corresponds to the tangent $X_0x + Y_0y + 1 = 0$ of the curve $M(1, x, y) = 0$ at a non-singular point (x_0, y_0) of the curve $M(1, x, y) = 0$. By this relation we can obtain the polynomial $L(X, Y)$ from the homogeneous polynomial $M(t, x, y)$. The polynomial $M(t, x, y)$ is defined as

$$\begin{aligned} M(t, x, y) &= \\ &= [t - (\phi_1(x, y) - \phi_2(x, y))][t - (\phi_1(x, y) - \phi_3(x, y))][t - (\phi_2(x, y) - \phi_1(x, y))] \\ &\quad \times [t - (\phi_2(x, y) - \phi_3(x, y))][t - (\phi_3(x, y) - \phi_1(x, y))][t - (\phi_3(x, y) - \phi_2(x, y))] \end{aligned}$$

where $\phi_j(x, y)$ ($j = 1, 2, 3$) satisfy the equation

$$\begin{aligned} \det(tI_3 + xH + yK) &= t^3 + t^2x - 4tx^2 - 4x^3 + 4xy^2 \\ &= (t - \phi_1(x, y))(t - \phi_2(x, y))(t - \phi_3(x, y)) \end{aligned}$$

for every $(x, y) \in \mathbb{C}^2$.

The polynomial $M(t, x, y)$ has integral coefficients and $L(X, Y)$ is obtained as a factor of the resultant $L_0(X, Y)$ of the polynomial

$$Y^6 M(1, x, -1/Y - xX/Y) = M(Y, xY, -1 - xX)$$

and its derivative with respect to x . By factorizing L_0 in the polynomial ring $\mathbb{Z}[t, x, y]$, we can obtain the polynomial $L(t, x, y)$. Popular computer softwares for symbolic calculation, e.g., “Mathematica”, “Maple”, etc, are available to perform such a factorization. In this example we find

$$M(t, x, y) = t^6 - 26t^4x^2 + 169t^2x^4 - 144x^6 - 560x^4y^2 + 432x^2y^4.$$

3. With flat portions in mind

We recall that a *supporting line* of a convex set $S \subset \mathbb{C}$ is a line containing a boundary point of S , throughout denoted by ∂S , and defining two half planes, such that one of them does not contain S . Suppose that the straight line

$$\ell = \{(x, y) \in \mathbb{R}^2 : ax + by + c = 0, a, b, c \in \mathbb{R}\}$$

is a supporting line of $W_C^J(A)$. If $\ell \cap \partial W_C^J(A)$ contains more than one point, then $\ell \cap \partial W_C^J(A)$ is called a *flat portion* on the boundary of $W_C^J(A)$. If A is J -normal, then $\partial W_C^J(A)$ is a union of flat portions as shown in Theorem 3.2.

Theorem 3.1. *Let $A = H + iK$, where $H = \Re^J(A)$ and $K = \Im^J(A)$ are J -Hermitian and H is J -unitarily diagonalizable with non interlacing eigenvalues. Let $\lambda'_1 > \cdots > \lambda'_s$ be the s distinct eigenvalues of H with respective multiplicities n_1, \dots, n_s . Let $C = C_1 \oplus \cdots \oplus C_s$, $J = J_1 \oplus \cdots \oplus J_s$, and*

$$K = \begin{pmatrix} K_{11} & K_{12} & \cdots & K_{1s} \\ K_{21} & K_{22} & \cdots & K_{2s} \\ \cdots & \cdots & \cdots & \cdots \\ K_{s1} & K_{s2} & \cdots & K_{ss} \end{pmatrix},$$

where $C_j, J_j, K_{jj} \in M_{n_j}$, $j = 1, \dots, s$. If at least one of the sets $W_{C_t}^{J_t}(K_{tt})$ does not reduce to a singleton, then $\partial W_C^J(A)$ has a flat portion parallel to the imaginary axis.

Proof. Let $H = \text{diag}(\lambda_1, \dots, \lambda_n)$ with $\lambda_1 \geq \cdots \geq \lambda_r > \lambda_{r+1} \geq \cdots \geq \lambda_n$, and $C = \text{diag}(c_1, \dots, c_n)$ with $c_{r+1} \geq \cdots \geq c_n > c_1 \geq \cdots \geq c_r$. So there exists a line parallel to the imaginary axis separating $\sigma_+^J(A)$ and $\sigma_-^J(A)$. Then by Theorem 1.1 of [1]

$$\{\text{tr}(CUHU^{-1}) : U \in \mathcal{U}_{r,n-r}\} = (-\infty, a_0], \quad a_0 = \sum_{j=1}^n c_j \lambda_j.$$

We show that

$$\begin{aligned} & \{\text{tr}(CUKU^{-1}) : \text{tr}(CUHU^{-1}) = a_0, U \in \mathcal{U}_{r,n-r}\} \\ &= W_{C_1}^{J_1}(K_{11}) + W_{C_2}^{J_2}(K_{22}) + \cdots + W_{C_s}^{J_s}(K_{ss}). \end{aligned}$$

In fact, if $\text{tr}(CUHU^{-1}) = a_0$, then there exist $V, W \in \mathcal{U}_{r,n-r}$ such that $U = WV$ and $WCW^{-1} = C$, $VHV^{-1} = H$. Without loss of generality we may assume that $H = (\lambda'_1 I_{n_1}) \oplus \cdots \oplus (\lambda'_s I_{n_s})$. Therefore, $V = V_1 \oplus \cdots \oplus V_s$, where V_j has size n_j and $V_j J_j V_j^* = J_j$, so that

$$VKV^{-1} = \begin{pmatrix} V_1 K_{11} V_1^{-1} & \cdots & V_1 K_{1s} V_s^{-1} \\ \vdots & \ddots & \vdots \\ V_s K_{s1} V_1^{-1} & \cdots & V_s K_{ss} V_s^{-1} \end{pmatrix}$$

and

$$\text{tr}(CUKU^{-1}) = \sum_{j=1}^s \text{tr}(C_j V_j K_{jj} V_j^{-1}).$$

Let ℓ be the supporting line of $W_C^J(A)$ parallel to the imaginary axis. Thus

$$\ell \cap \partial W_C^J(A) = \left\{ a_0 + i \sum_{j=1}^s \operatorname{tr}(C_j V_j K_{jj} V_j^{-1}) : V_j J_j V_j^* = J_j \right\}.$$

This intersection is a singleton if and only if each summand of the above Minkowski sum is a singleton, namely $\sum_{j=1}^n c_j \alpha_j$. If in the above sum there exists at least one set $W_{C_t}^{J_t}(K_{tt})$ which is not a singleton, then $\ell \cap \partial W_C^J(A)$ is a line segment, a half-line or the whole line according to the following. If $n_1 + \dots + n_t = r$, then, for some k , $W_{C_k}^{J_k}(K_{kk}) = W_{C_k}(K_{kk})$ is a line segment and $\ell \cap \partial W_C^J(A)$ is also a line segment. If $n_1 + \dots + n_t < r < n_1 + \dots + n_{t+1}$ and $W_{C_{t+1}}^{J_{t+1}}(K_{t+1,t+1})$ is a singleton, then $\ell \cap \partial W_C^J(A)$ is still a line segment. Otherwise, this intersection is a half-line of ℓ or the whole line ℓ . The result follows. \square

Let $C = \operatorname{diag}(c_1, \dots, c_n)$ with $c_{r+1} \geq \dots \geq c_n > c_1 \geq \dots \geq c_r$. We also assume that $A = \operatorname{diag}(\alpha_1, \dots, \alpha_n)$, $\sigma_+^J(A) = \{\alpha_1, \dots, \alpha_r\}$ and $\sigma_-^J(A) = \{\alpha_{r+1}, \dots, \alpha_n\}$. Let S_n denote the symmetric group of degree n and let $S_{r,n-r}$ be the set of permutations of the form $\sigma = \sigma_1 \circ \sigma_2$, where $\sigma_1, \sigma_2 \in S_n$ are such that $\sigma_1(j) = j$, $j \in \{r+1, \dots, n\}$ and $\sigma_2(j) = j$, $j \in \{1, \dots, r\}$. The $r!(n-r)!$ points

$$z_\sigma = \sum_{j=1}^n c_j \alpha_{\sigma(j)}, \quad \sigma \in S_{r,n-r}, \quad (6)$$

belong to $W_C^J(A)$ and are the so-called σ -points.

For a fixed $\sigma \in S_{r,n-r}$ and $k, l \in \{1, \dots, r\}$ or $k, l \in \{r+1, \dots, n\}$, the $\frac{r(r-1)}{2} + \frac{(n-r)(n-r-1)}{2}$ line segments

$$\ell_{k,l}^\sigma = \left\{ \sum_{j=1}^n c_j \alpha_{\sigma(j)} - t(\alpha_{\sigma(k)} - \alpha_{\sigma(l)})(c_k - c_l) : 0 \leq t \leq 1 \right\} \quad (7)$$

are contained in $W_C^J(A)$. The line segment $\ell_{k,l}^\sigma$ is generated by the J -unitary matrices obtained from the identity replacing the entries (k, k) , (k, l) , (l, k) , (l, l) respectively by $\cos \theta$, $-\sin \theta$, $\sin \theta$, $\cos \theta$.

For a fixed $\sigma \in S_{r,n-r}$ and $l \in \{1, \dots, r\}$, $k \in \{r+1, \dots, n\}$, the $r(n-r)$ half-lines

$$\mathcal{L}_{k,l}^\sigma = \left\{ \sum_{j=1}^n c_j \alpha_{\sigma(j)} + t(\alpha_k - \alpha_l) : 0 \leq t < \infty \right\} \quad (8)$$

are contained in $W_C^J(A)$. The ray $\mathcal{L}_{k,l}^\sigma$ is generated by the J -unitary matrices obtained from the identity replacing the entries $(k, k), (k, l), (l, k), (l, l)$ respectively by $\cosh \theta, \sinh \theta, \sinh \theta, \cosh \theta$.

Theorem 3.2. *Let $J = I_r \oplus -I_{n-r}$ and let $A = \text{diag}(\alpha_1, \dots, \alpha_n)$ be a J -normal matrix such that there exists a line separating $\sigma_+^J(A) = \{\alpha_1, \dots, \alpha_r\}$ and $\sigma_-^J(A) = \{\alpha_{r+1}, \dots, \alpha_n\}$. Let $C = \text{diag}(c_1, \dots, c_n)$ with $c_{r+1} \geq \dots \geq c_n > c_1 \geq \dots \geq c_r$. Then*

$$W_C^J(A) = \text{Co} \left\{ \mathcal{L}_{k,l}^\sigma : \sigma \in S_{r,n-r}, l = 1, \dots, r, k = r+1, \dots, n \right\},$$

where $\text{Co} \{ \cdot \}$ denotes the convex hull of $\{ \cdot \}$.

Proof. Since $W_C^J(A)$ is convex, then

$$\text{Co} \left\{ \mathcal{L}_{k,l}^\sigma : \sigma \in S_{r,n-r}, l = 1, \dots, r, k = r+1, \dots, n \right\} \subseteq W_C^J(A).$$

Next we show that the reversed inclusion also holds. Let z be an arbitrary point in $\partial W_C^J(A)$. Then z is either a corner or a regular point. If z is a corner, then it is a σ -point. If z is a regular point there exists a unique supporting line to $W_C^J(A)$ passing through it. Let $A = e^{-i\theta}(H_\theta + iK_\theta)$, and so H_θ and K_θ commute due to the J -normality of A . Assume that H_θ has s distinct eigenvalues, $\lambda'_1 = \lambda_1, \lambda'_2 = \lambda_{n_1+1}, \dots, \lambda'_s = \lambda_{n_1+\dots+n_{s-1}+1}$ with multiplicities n_1, \dots, n_s , respectively. Then H_θ and K_θ are simultaneously J -unitarily diagonalizable, being n_1, \dots, n_s the sizes of the diagonal blocks. Analogously to Theorem 3.1, we may conclude that

$$\ell_\theta \cap \partial W_C^J(A) = \left\{ a_0 + i \sum_{j=1}^s \text{tr}(C_j V_j K_{jj} V_j^{-1}) : V_j J_j V_j^* = J_j \right\},$$

where ℓ_θ is the supporting line perpendicular to the direction $\arg(z) = -\theta$. This intersection is a singleton if and only if each summand of the above Minkowski sum is a singleton and reduces to $\sum_{j=1}^n c_j \alpha_{\sigma(j)}$ for a certain $\sigma \in S_{r,n-r}$. If in the above sum there exists at least one set $W_{C_t}^{J_t}(K_{tt})$ which does not reduce to a singleton, then $\ell_\theta \cap \partial W_C^J(A)$ is a line segment, a half-line or the whole line. \square

Remark 3.1. According to Theorem 3.2, $\partial W_C^J(A)$ is a convex polygon if A is J -normal. Next we present an example of a non J -normal A for which $\partial W_C^J(A)$ is still a convex polygon. Consider $J = \text{diag}(1, 1, 1, 1, -1)$, $C = \text{diag}(1, 0, 0, 0, 0)$ and

$$A = \begin{pmatrix} 1+i & 0 & 0 & 0 & 0 \\ 0 & 1-i & 0 & 0 & 0 \\ 0 & 0 & 2 & b & 0 \\ 0 & 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 0 & -1 \end{pmatrix},$$

with $b \in \mathbb{R}$. We have

$$\Re^J(e^{-i\theta}A) = \begin{pmatrix} \cos\theta + \sin\theta & 0 & 0 & 0 & 0 \\ 0 & \cos\theta - \sin\theta & 0 & 0 & 0 \\ 0 & 0 & 2\cos\theta & \frac{b}{2}e^{-i\theta} & 0 \\ 0 & 0 & \frac{b}{2}e^{i\theta} & 2\cos\theta & 0 \\ 0 & 0 & 0 & 0 & -\cos\theta \end{pmatrix},$$

with

$$\sigma_+^J(\Re^J(e^{-i\theta}A)) = \left\{ 2\cos\theta + \frac{b}{2}, 2\cos\theta - \frac{b}{2}, \cos\theta + \sin\theta, \cos\theta - \sin\theta \right\}$$

$$\sigma_-^J(\Re^J(e^{-i\theta}A)) = \{-\cos\theta\}.$$

If $b \leq 2$ and $-2 \leq \tan\theta \leq 0$, the smallest eigenvalue in $\sigma_+^J(\Re^J(e^{-i\theta}A))$ is $\cos\theta - \sin\theta$, so that $1-i$ is a corner of $\partial W_C^J(A)$. If $b \leq 2$ and $0 \leq \tan\theta \leq 2$, the smallest eigenvalue in $\sigma_+^J(\Re^J(e^{-i\theta}A))$ is $\cos\theta + \sin\theta$, so that $1+i$ is a corner of $\partial W_C^J(A)$. Then, it follows trivially from Theorem 3.1 that

$$W_C^J(\Re^J(e^{-i\theta}A)) = [1+i, 1-i] \cup \{1+i+(2+i)t : t \geq 0\} \cup \{1-i+(2-i)t : t \geq 0\}.$$

If $b = 3$ and $-\pi/3 \leq \theta \leq \pi/3$, the smallest eigenvalue in $\sigma_+^J(\Re^J(e^{-i\theta}A))$ is $2\cos\theta - b/2$. Then, easy calculations based on Theorem 3.1 show that

$$W_C^J(\Re^J(e^{-i\theta}A)) = \left\{ 2 + \frac{3}{2}e^{i\phi} : \frac{2\pi}{3} \leq \phi \leq \frac{4\pi}{3} \right\}$$

$$\cup \left\{ \frac{5+i3\sqrt{3}}{4} + (1+i\sqrt{3})t : t \geq 0 \right\} \cup \left\{ \frac{5-i3\sqrt{3}}{4} + (1-i\sqrt{3})t : t \geq 0 \right\}.$$

In this case there are no corners in $\partial W_C^J(A)$. For $b = 6$, $W_C^J(A)$ is the right half plane defined by $x = 1$. For $b > 6$, $W_C^J(A)$ is the whole complex plane.

Theorem 3.3. *Let J, C and A be under the conditions of the Theorem 3.2. If $z \in \partial W_C^J(A)$, then one of the following assertions holds:*

- (i) z is a σ -point;
- (ii) $z \in [z_{\sigma'}, z_{\sigma''}]$, where $\sigma', \sigma'' \in S_{r, n-r}$ differ by a transposition;
- (iii) $z \in \{z_{\sigma} + t(\alpha_k - \alpha_l) : t \geq 0\}$, for some $l \in \{1, \dots, r\}$, $k \in \{r+1, \dots, n\}$.

Proof. By Theorem 3.1, $W_C^J(A)$ is the closed convex-hull of the half-lines (8). If $z \in \partial W_C^J(A)$, having in mind that $\partial W_C^J(A)$ is a convex curve, then z is a corner or a regular point. In the first case, z is a σ -point. If z is a regular point, let $\pi/2 - \theta$ be the slope of the supporting line passing through z . By a perturbation, we may suppose that the eigenvalues of A define $\binom{n}{2}$ distinct directions. Then H_{θ} has precisely one double eigenvalue and the intersection of that supporting line with $\partial W_C^J(A)$ is either a line segment, whose endpoints are σ -points which differ by a transposition, or a half-ray of the stated type. \square

Theorem 3.4. *Let $A \in M_n$. If $\Re^J(e^{-i\theta} A)$ has imaginary eigenvalues for any $\theta \in \mathbb{R}$, then $W_C^J(A)$ is the whole complex plane. If the spectrum of $\Re^J(e^{-i\theta_0} A)$ is real for $\theta = \theta_0$ and $\Re^J(e^{-i\theta} A)$ has imaginary eigenvalues for $\theta \neq \theta_0$, then $W_C^J(A)$ is either a half plane or the whole complex plane.*

Proof. If for any $\theta \in \mathbb{R}$, the matrix $\Re^J(e^{-i\theta} A)$ has imaginary eigenvalues, then the projection of $W_C^J(A)$ on the line with slope $\pi/2 + \theta$ is the whole line. If there exists a unique $\theta_0 \in \mathbb{R}$, such that the spectrum of $\Re^J(e^{-i\theta_0} A)$ is real, then the projection of $W_C^J(A)$ on the line with slope $\pi/2 + \theta_0$ is either the whole line or a half-line by Theorem 1.1 of [1]. \square

4. Numerical algorithm and Examples

Based on Westwick's theorem, Li *et al* [5] provided an algorithm to plot $\partial W_C(A)$ for C a Hermitian matrix. A numerical algorithm to draw the boundary of $W_C^J(A)$ for an arbitrary $A \in M_n$ and C a J -Hermitian matrix is here presented. Theorem 2.1, Lemma 5.3 and Theorem 1.1 of [1] provide the general principle. Our approach uses the elementary idea that $\partial W_C^J(A)$ may be traced by computing the supporting lines of $W_C^J(A)$ as specified below. The accuracy is quite good.

Algorithm

Step 1: For an arbitrary complex matrix $A \in M_n$, an involutive Hermitian matrix $J \in M_n$ and a real matrix $C = \text{diag}(c_1, \dots, c_n)$, compute the eigenvectors of C , v_j , $j = 1, \dots, n$ and construct two vectors formed by the eigenvalues of C in $\sigma_+^J(C)$ and in $\sigma_-^J(C)$. If they do not interlace, go to Step 2. Otherwise, go to Step 8 and we have a degenerate case.

Step 2: Compute the eigenvalues of the matrix $H_{\theta_k} := \Re^J(e^{-i\theta_k} A)$, with

$$\theta_k = \frac{\pi(k-1)}{2m} \quad (9)$$

for some positive integer m and for $k = 1, \dots, 2m$. Construct the vector formed by all the values of k such the matrix H_{θ_k} has real spectrum with anisotropic eigenvectors. If this vector is nonempty, go to Step 3. Otherwise, go to Step 8 and we have a degenerate case.

Step 3: For each θ_k described above, compute the eigenvalues of the matrix H_{θ_k} , and the associated eigenvectors $u_j(k)$, $j = 1, \dots, n$. Construct two vectors formed by the eigenvalues of H_{θ_k} in $\sigma_+^J(H_{\theta_k})$ and in $\sigma_-^J(H_{\theta_k})$.

Step 4: Investigate the existence of directions for which the eigenvalues of the matrix H_{θ_k} do not interlace. If these directions exist and are not all the directions given by (9), go to Step 5. Otherwise, follow to Step 8.

Step 5: Let r and $n - r$ be the number of eigenvalues of C in $\sigma_+^J(C)$ and $\sigma_-^J(C)$. For each $k = 1, \dots, 2m$, compute the $r!(n-r)!$ points

$$z_\sigma(\theta_k) = \sum_{s=1}^n c_s \lambda_\sigma(H_{\theta_k}),$$

where $\sigma = \sigma_1 \circ \sigma_2 \in S_{r,n-r}$ and $\lambda_1, \dots, \lambda_n$ are the eigenvalues of H_{θ_k} .

Step 6: Since the eigenvalues of C , as well as those of each H_{θ_k} , do not interlace, we can have one of the two relations given in (4). So, if the relation (4) is the same for the eigenvalues of the matrices C and H_{θ_k} , we put $\lambda(k) := \min z_\sigma(\theta_k)$. Otherwise, $\lambda(k) := \max z_\sigma(\theta_k)$.

Step 7: For each $k = 1, \dots, 2m$, plot the supporting line of $W_C^J(A)$ defined by:

$$x \cos(\theta_k) - y \sin(\theta_k) = \lambda(k).$$

Step 8: (Degenerate cases) Compute

$$\sum_{s=1}^n c_s \frac{\zeta_{j_s}^* J A \zeta_{j_s}}{\zeta_{j_s}^* J \zeta_{j_s}},$$

for a sample of anisotropic vectors $\zeta_j = (\zeta_{j_1}, \dots, \zeta_{j_n})$ randomly chosen. The distribution of these points allows to conclude whether $W_C^J(A)$ is the complex plane (possibly an half-plane) or a line (possibly an half-line).

Remark 4.1. Obviously, if $J = I, -I$, then $W_C^J(A)$ reduces to the C -numerical range and our algorithm and program also work in this case. Its speed and accuracy are equivalent to those of the program in [5].

We illustrate the algorithm with the following examples. All the figures presented in this note were generated by our *Matlab* program available at the following website: <http://www.mat.uc.pt/~bebiano>.

Example 4.1. Let $J = I_2 \oplus -I_2$, $C = \text{diag}(2, 1, -1, -2)$ and let

$$A = \begin{pmatrix} 2 & i & 0 & 0 \\ i & 1 & i & 0 \\ 0 & -i & -1 & -i \\ 0 & 0 & -i & -2 \end{pmatrix}.$$

$W_C^J(A)$ is represented in Figure 1 by the supporting lines.

Example 4.2. Let $J = I_2 \oplus -I_2$, $C = \text{diag}(2, 1, -1, -2)$ and let

$$A = \begin{pmatrix} 2 & i & 0 & 0 \\ i & 2 & i & 0 \\ 0 & -i & -1 & -i \\ 0 & 0 & -i & -2 \end{pmatrix}.$$

$W_C^J(A)$ is represented in Figure 2 by the supporting lines. The line segment $[10 + i, 10 - i]$ is contained in the boundary.

Example 4.3. Let $J = I_2 \oplus -I_2$, $C = \text{diag}(2, 1, -1, -2)$ and

$$A = \text{diag}(3 + 2i, 1 - i, -1 + i, -3 - 2i).$$

In this case,

$$\partial W_C^J(A) = \{10 + (1 - i)t : t \geq 0\} \cup [10, 14 + 6i] \cup \{14 + 6i + (3 + 2i)t : t \geq 0\},$$

and $W_C^J(A)$ is represented in Figure 3 by the supporting lines.

FIGURE 1. Supporting lines of $W_C^J(A)$, for J, C and A as in Example 4.1.

FIGURE 2. Supporting lines of $W_C^J(A)$, for J, C and A as in Example 4.2.

FIGURE 3. Supporting lines of $W_C^J(A)$, for J, C and A as in Example 4.3.
